Abiotic and biotic stresses
Soil-borne pathogens

ABSTRACT

Trichoderma spp. are among the front-line microorganisms commonly employed in novel biotechnology applications. They have been well-proven as biopesticides, biofertilizers, and biostimulants for managing plants against biotic and abiotic stresses. They are instrumental in managing plant diseases of economic importance, such as tomato root rot. However, this group of fungi has not been well-exploited en-mass in developing countries, while the use of bioagents in-lieu of chemical pesticides is still not a common practice in many African countries. Africa contributes 11.8% to global tomato production. Unfortunately, more than half of the actual product is lost due to diseases. The root rot of tomatoes predominantly caused by soil-borne fungal pathogens are among significant problems of tomato cultivation in Africa. Here, we review the constraints of tomato root rot in Africa and the roles of *Trichoderma* in repositioning the crop for optimum productivity. We gave a comprehensive overview of the economic importance, root rot epidemiology, and how to circumvent it through gene pool to resistant tomato and employ *Trichoderma*'s biological control potentials. Furthermore, this review gives an overview of the mechanisms of action of *Trichoderma*, gaps in the advocacy, adoption, commercialization, and regulation of *Trichoderma* as biocontrol agents of tomato rot diseases in Africa.

1. Introduction

Tomato (*Solanum lycopersicum* L.) is the world's most widely eaten vegetable belonging to Solanaceae. It is a crop extensively grown worldwide, rich in potassium, antioxidants, ascorbic acid, vitamin A, lycopene, and tocopherols for nourishing human health (Capobianco-Uriarte et al., 2021). Africans are part of significant tomato producers. Africa accounts for 11.8% of global production, while Asia, Europe, and America produce 61.1%, 13.5%, and 13.4% of the total tomato yield, respectively (Quinet et al., 2019). Based on tomato productivity, Egypt (6.8 million tonnes) is the leading tomato producer in Africa, followed by Nigeria (3.8 million tonnes), while South Africa (630 thousand tonnes) is the least producer of tomatoes (Dube et al., 2020). However, its output in Africa is mainly reduced by various factors, including biotic constraints. Attacks by different viral, bacterial, arthropod pests, and fungal diseases are poorly controlled, contagious, and may swiftly spread from plant to plant in a tomato field when appropriate conditions (Ochilo et al., 2019).

The root rot of tomato, in particular, is commonly caused by soil-borne fungal pathogens such as *Rhizoctonia solani*, *Fusarium solani*, *Phytophthora* species, and *Sclerotium rolfsii* that delays growth, reduce harvest yield and quality, and subsequent death of severely infected plants (Ajilogba et al., 2013a; Hamza et al., 2016; Kashyap et al., 2020). This disease is favored by environmental factors such as temperature for pathogen growth, moderate to high soil moisture content, soil compaction, poor drainage, and other factors that contribute to plant stress (Sharath Chandran et al., 2021). Root rot was revealed to reduce the yield of tomatoes by up to 25% in developed countries and more than 50% in developing countries (Nicastro and Carillo, 2021). This is a big challenge considering the multi-pathogenic cause of this disease and poor technologies for its management.

Enormous success has been recorded on plant disease control via a variety of methodologies like the use of independent disease management, plant breeding for resistant varieties/genetically modified plants, use of agrochemicals/excellent agronomic and horticultural practices, as well as biological control agents (Ajilogba and Babalola, 2013b; Ons,

E-mail address: olubukola.babalola@nwu.ac.za (O.O. Babalola).

2020). Using fungi as biological control agents is an essential, economically viable, environmentally safe, and long-term strategy for plant disease management that many developed countries are already implementing (Figlan et al., 2020; Olowe et al., 2020). *Trichoderma* species have been reported as excellent mycofungicides (Babu and Pallavi, 2013; Woo et al., 2014; Kuzmanovska et al., 2018; Manandhar et al., 2019). They are good bioagents with excellent competitive attributes in the rhizosphere, intense aggressiveness against phytopathogenic fungi, and aided suppression mechanisms (Filizola et al., 2019). They have a high tolerance to soil-applied agrochemicals, modify the rhizosphere for plants benefits, can utilize any available soil nutrients efficiently, survive under unfavorable conditions, and promote plant growth (Vinale et al., 2008; Köhl et al., 2019).

Biological control has not yet been widely used in Africa due to concerns about its efficacy, a lack of expertise, high costs, technological compatibility, and a lack of technical assistance (Ons et al., 2020). Despite many results on in-vivo antagonistic effects of native African *Trichoderma* species on different plant pathogens, especially on common soil-borne pathogens such as *Rhizoctonia* and *Fusarium*, they have not been fully explored as tools for the management of crop diseases and their use as biological products in Africa (del Carmen et al., 2021). In most developing countries, most farmers cannot utilize disease management practices because of financial constraints, limited knowledge, and research on different alternatives (Kuehne et al., 2017). Most African farmers lack the physical access and financial means to technical solutions (Perez et al., 2017) but revert to alternatives such as pesticides and local irrigation. This could contribute to tackling disease resistance and other pertinent issues currently faced by African farmers (Rush et al., 2021).

This review again affirms *Trichoderma* species as bioresources with potential application for adequate control/management of root rot disease of tomatoes in Africa; their mechanism of action, efficacy, application style, and packaging were discussed. Their roles, if well implemented in the management of tomato root rot with good commercial strategies, policy, and advocacy in Africa, indeed hold a potential breakthrough for the management of root rot disease of tomatoes.

2. Tomato production in Africa and root rot disease

2.1. Economic importance of tomatoes in Africa

Tomato is the most widely consumed vegetable in Africa (Rwomushana et al., 2019). In 2019, more than 21 million tons of tomatoes were produced in Africa, with a production increase of more than 60% in the last 20 years (FAOSTAT, 2021). The area with the highest tomato production is Saharan Africa, Egypt, Algeria, Morocco, and Tunisia, while Nigeria is the biggest producer among sub-Saharan countries (FAOSTAT, 2021). The cultivation of tomatoes is also essential from a socio-economical point of view since it represents a significant source of income for rural producers in several developing African countries (Arah, 2015; Mulugeta et al., 2020). It also offers employment to women, who represent more than 60% of the labor force in this cultivation (Rwomushana et al., 2019).

However, tomato yields in Africa are still far below their estimated potential due to some abiotic stresses (climate change, low soil fertility, drought, high temperatures) and biotic stresses (microbial plant pathogens, insect pests, weeds). It has been estimated that in most sub-Saharan countries, the actual tomato yield is only 10–30% of the estimated potential production (Nordey et al., 2020).

2.2. Root rot of tomatoes: epidemiology and susceptibility in Africa

Many varieties of tomatoes have been developed and distributed widely in Africa. In Kenya, tomato varieties such as Assila F1, Eden F1, Milele F1, Rambo F1, Kilele F1, Shanty improved, Star 9065, Eva F1, Tylka F1, Steve F1, and different companies have developed many more

for greenhouse and open ground cultivation. These varieties have been developed for high yielding, high shelf-life and resistance to diseases like *Alternaria solani* (As) Fusarium wilt (Fol), Fusarium Crown and Root Rot (Fol), Nematodes (N), Tomato Yellow Leaf Curl Virus (TYLCV), and Verticillium wilt (Vd). Root rot of tomato plants is a serious and common problem worldwide. Its symptoms include not only browning and softening of root tips and root lesions but also wilted leaves, stunted plant growth, and reduced yield (Williamson-Benavides and Dhingra, 2021). The causal agents for tomato root rot can be numerous fungi, and they can also vary according to the geographical region. Unfortunately, there is no general compendium of tomato root rot epidemiology for the whole African continent, and this phenomenon remains unstudied, mainly in most African countries. More studies managed to isolate the causal fungal pathogens of tomato root rot in Egypt (El-Mougy et al., 2011), followed by Nigeria (Ewekeye and Odebode, 2021) and Algeria (Yezli et al., 2019), and South Africa (Thabet and Khalifa, 2018). Based on the available literature, the most common root rot fungal pathogen for tomatoes in Africa is *Fusarium oxysporum* Schleld., it has been reported from Egypt, Algeria, and Nigeria. *F. oxysporum* is a ubiquitous soil-borne pathogen with approximately 150 *formae speciales* that can infect a wide range of plants (Pareek and Rajam, 2017).

The *F. oxysporum* f. sp. *radicis-lycopersici* Jarvis and Shomaker (FORL) is most commonly associated with tomato root rot in Africa. This strain of *Fusarium* is highly virulent and affects tomato-growing areas worldwide (Debbi et al., 2018). Strains of FORL have been isolated from Egypt on tomato plants with root rot in the Giza Governorate (Mosa and Youssef, 2021), in El-Ismailia, El-Tahrir, and El-Fayoum, while no exact sampling site was specified by El-Abeid et al. (2020) and Shenashen et al. (2017). These strains have also been found associated with diseased tomato plants in the Algerian Sahara (Goudjal et al., 2016) and in the Algerian regions of Biskra, Boumerdes, Algiers, Mostaganem, and Jijel (Debbi et al., 2018). Another strain of the *F. oxysporum* group which is often associated with tomato root rot is f. sp. *lycopersici* (Sacc.) Snyder and Hansen (FOL) was isolated from the Algerian regions of Boumerdes, Algiers, Bikra, Jijel, and Tipaza (Debbi et al., 2018), and in Nigeria, in the Obio-Akpore Local Government of Rivers State (Wokoma, 2008). In other cases, it was not possible to discern the *formae speciales*. There is only the indication of *Fusarium oxysporum* at the species level, such as in Ibadan, Nigeria (Etaware and Oyetuji, 2019), in Jijel, Algeria (Debbi et al., 2018), and in Egypt (Muhamma et al., 2016). The other two species of *Fusarium* associated with tomato root rot were found in Africa; the first one is *Fusarium solani* (Mart.) Sacc., isolated at Beni Suef and Fayoum governorates in Egypt (Elshahawy et al., 2018), while the second one, *Fusarium equiseti* (Corda) Sacc. was isolated for the first time from tomato plants affected by the crown and root rot in Algeria and completed Koch's postulates (Yezli et al., 2019).

A species that is often found associated with tomato root rot in African literature is *Rhizoctonia solani* J.G. Kühn (Williamson-Benavides and Dhingra, 2021). This basidiomycete is a soil-borne pathogen that can severely damage tomato plants and reduce their yield (Nikraftar et al., 2013). This pathogen was isolated in Egypt from diseased plants, for example, in the El-Behira governorate (Heflich et al., 2021) and other unspecified tomato fields (Muhamma et al., 2016; Hamza et al., 2016). It was also discovered in Nigeria, in the Obio-Akpore Local Government of Rivers State (Wokoma, 2008). Another possible cause of tomato root rot is the oomycetes *Pythium* and *Phytophthora*. *Pythium* generally causes damage to the hypocotyl of the seedling, followed by stunted growth and often plant death. Specifically, *Pythium aphanidermatum* (Edson) Fitzpatrick is one of the most common causal agents of tomato root rot all over the world (Christy Jeyaseelan et al., 2012), and it was isolated for the first time in Egypt in 2018, at Beni Suef and Fayoum governorates (Elshahawy et al., 2018). This pathogen was also isolated near Barberton and Pretoria in South Africa and Selebi Phikwe in Botswana (Labuschagne et al., 1994). Moreover, another member of the genus *Pythium*, *P. perplexum* H. Kouyeas & Theoh., was isolated from hydroponic tomato cultivations in South Africa (Gull et al., 2004). On the other hand,

regarding *Phytophthora*, there is the first record of *Phytophthora capsici* Leonian as the causal agent of tomato root rot in South Africa (near Barberton and Pretoria) and Botswana (Srelebi Phikwe) in 1994 (Labuschagne et al., 1994). Moreover, *Macrophomina phaseolina* (Tassi) Goid., another soil-borne fungus that invades tomato plants through roots, was isolated from naturally infected roots from tomato plants showing root rot symptoms in Egypt (Muhamma et al., 2016).

3. *Trichoderma*, an untapped resource for the management of tomato root rot in Africa

Excessive application of synthetic chemical pesticides and inorganic fertilizers to control plant pathogens has been rebuked due to their ecological impact. In contrast, biopesticides and biological control methods have been well advocated (Wang and Zhuang, 2019). Many researchers have justified using biological control methods in place of chemical control due to its environmental friendliness and cost-effectiveness (Contreras-Cornejo et al., 2020; Moosavi and Zare, 2012). *Trichoderma* is a group of ascomycete fungal Genus of Order-Hypocreales, Family-Hypocreaceae. They are ubiquitous and widely distributed in diverse environments. *Trichoderma* fungi have for long been reported as decomposers (Druzhinina et al., 2006), many authors have reported them as saprobic organisms, while many reports are emerging on many species of *Trichoderma* as mycoparasitic and endophytic organisms (Harman et al., 2004; Samuels et al., 2006; Mukherjee et al., 2013). *Trichoderma* species are well known as biological control agents (BCA) against various plant pathogens ranging from viral, bacteria, fungi, nematodes, protozoans, insect, plant, or animal pathogens (Samuels, 1996; Woo et al., 2006). Many mycoparasitic *Trichoderma* species have been well characterized for biocontrol of different fungal pathogens of plants.

Persoon (1794) first described this group of fungi and was later linked to a sexual state in the Hypocreales species. The first detailed work on identifying these fungi was made by Rifai (1969) and later expanded by Samuels (2006). They are well known for their role in either enhancing the plant growth and development, inducing resistance in plants against pathogens, enhancing the rhizosphere, or directly attacking the plant pathogens (Harman et al., 2004; Schuster and

Schmoll, 2010; Pandya et al., 2011; Keswani et al., 2014). Since *Trichoderma* can grow in different habitats, these abilities have made them very popular among the science community. As a result, several works have been published on the importance of *Trichoderma* in agriculture and plant disease control. Their mode of action against plant pathogens is shown in Fig. 1.

- (i) **Competition**, they compete to inhibit the growth of pathogens by starving or depriving plants of accessing basic life needs (Alabouvette et al., 2009). Many *Trichoderma* strains have been reported to be capable of secreting substances like siderophores to starve pathogens of essential elements (Latorre et al., 2001). Also, cellulose, glucan, and chitin to reduce carbon availability (Chet et al., 1997), and proteins to enhance root colonization as protection against pathogens (Saloheimo et al., 2002; Viterbo et al., 2004; Brotman et al., 2008; Samolski et al., 2012).
- (ii) **Antibiosis**, by the production of toxic substances like gliovirin, harzianic acid, alamethicins, tricholin, peptaibols, antibiotics, 6-pentyl- α -pyrone, massoilactone, viridin, glisoprenins, and heptelidic acid, polyketide, peptaibol, flocculosin, and terpenoid/steroid (Rey et al., 2001; Vey et al., 2001; Raaijmakers et al., 2009).
- (iii) **Mycoparasitism**, a condition where *Trichoderma* fungi can parasitize or grow on the fungal pathogens of plants to inhibit their growth. These groups have been well explored for the biological control of many plant pathogens (Zeilinger et al., 1999). This involves direct attacks by penetrating the cells of the pathogen and obtaining nutrients from them (Harman et al., 2004).
- (iv) **Induced resistance**, *Trichoderma* can interact with plants to trigger resistance against pathogens or disease. This, unlike others, is an indirect action of *Trichoderma* against plant pathogens. The first demonstration of induced resistance by *T. harzianum* strain T-39 was confirmed on bean plants against *B. cinerea* and *Colletotrichum lindemuthianum* (Bigirimana et al., 1997). This fungus has been reported to enhance the resistance of 10 different dicots and monocots against bacterial infections caused by *Xanthomonas* spp., and *Pseudomonas syringae*. Including the fungal infections caused by *B. cinerea*, *R. solani*, *Colletotrichum*

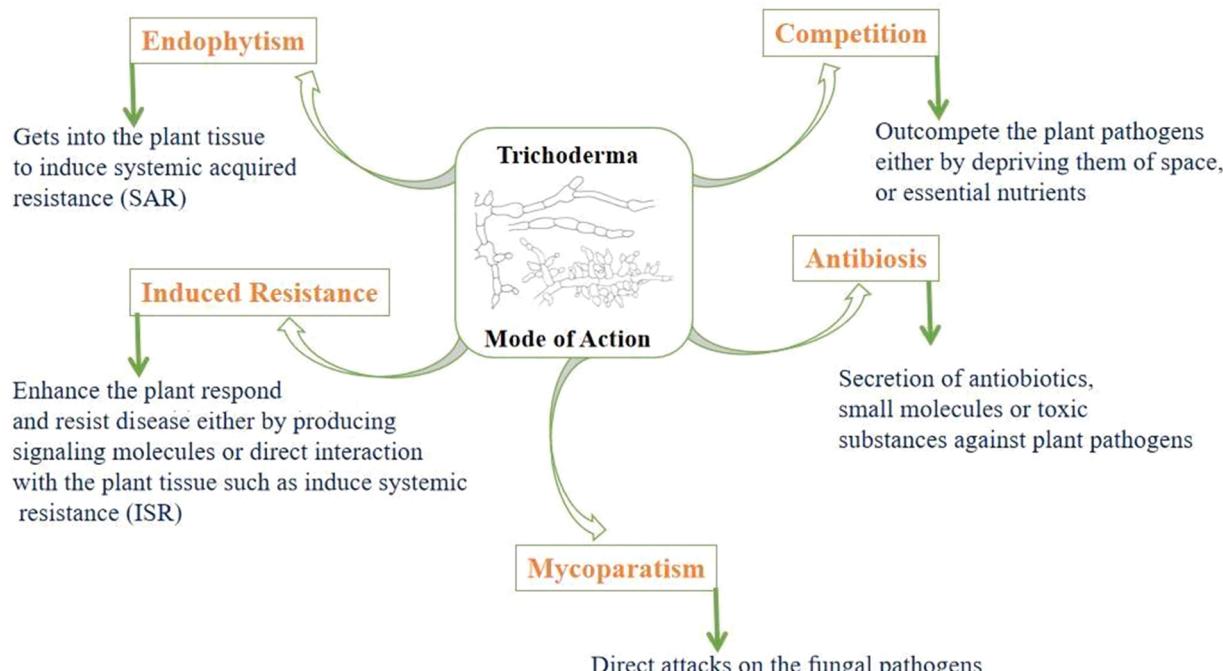

Fig. 1. *Trichoderma* modes of action as bioagent.

spp., *Phytophthora* spp., *Alternaria* spp., and *Magnaporthe grisea*; as well as CMV virus (De Meyer et al., 1998). This capability was established in *T. harzianum* T-22 in model plants (Contreras-Cornejo et al., 2011; Salas-Marina et al., 2011; Yoshioka et al., 2012; Harman et al., 2012). Other *Trichoderma* strains such as *T. virens*, *T. asperellum*, *T. harzianum*, and *T. atroviride* have been proven to stimulate the metabolism of their plant hosts against pathogens (Fig. 2).

(v) **Endophytes** grow inside the tissue of their plant hosts without harming them. This phenomenon is similar to induced resistance, but in this case, the plants are induced with resistance against disease caused by abiotic stress causes like drought, toxins, or radiation (Piotrowski and Volmer, 2006; Gazis and Chaverri, 2010; Chaverri and Gazis, 2011). The endophytic association between *Trichoderma* and their host plant is in most times, reported as mutually beneficial, although it may require complex interactions from direct contact to internal tissue colonization (Qin and Zhuang, 2016). The endophytic *Trichoderma* may act as commensals or as true symbionts that stimulate defense mechanisms in their host plants. The mechanism of how these fungi induce disease defense in their host plants has been well studied. They can either induce plant defense against pests, external abiotic stress, promoting their growth and photosynthesis rate, or contribute to their solubilization and uptake of nutrients from the soil (Vinale et al., 2008; Shores et al., 2010; Hermosa et al.,

2012; Harman et al., 2019; Hyde et al., 2019; Ikram et al., 2019; Kiarie et al., 2020).

Trichoderma spp. are particularly popular for different biological activities and have been well studied over the last two decades (Jiang et al., 2016; Chaverri et al., 2015). As such, many reputable fungal species have emerged under this group, but many studies on reporting new valuable species are often conducted mostly in Asia, Europe, and the United States (Kubicek et al., 2003; Qin and Zhuang, 2016; Chen and Zhuang, 2017; a&b; Inglis et al., 2020). *Trichoderma* strains have a good reputation in the management of tomato plants. Several species of *Trichoderma* have been reported either for the management of Tomato diseases and/or improving plant growth (Table 1). However, Africa has not yet been well covered in terms of quality studies on assessing or characterizing indigenous *Trichoderma* fungi. Some studies have detailed the diversity of *Trichoderma* in the soil at some specific regions of South Africa (du Plessis et al., 2018). In the case of the endophytic and plant-growth-promoting *Trichoderma* strains, studies are much limited in Africa at large. A study was carried out by del Carmen et al. (2021), which characterized the *Trichoderma* endophytes from Coffee plants, while some other authors isolated the *Trichoderma* strains from the rhizosphere from *Coffea arabica* in Ethiopia (Mulaw et al., 2010; Carmen et al., 2021). Studies that analyzed the effect of these fungi on perennial crops, particularly on the wild types, have revealed that they contain novel taxa that can be of great importance in carefully explored, important wild-type indigenous strains of *Trichoderma* have been

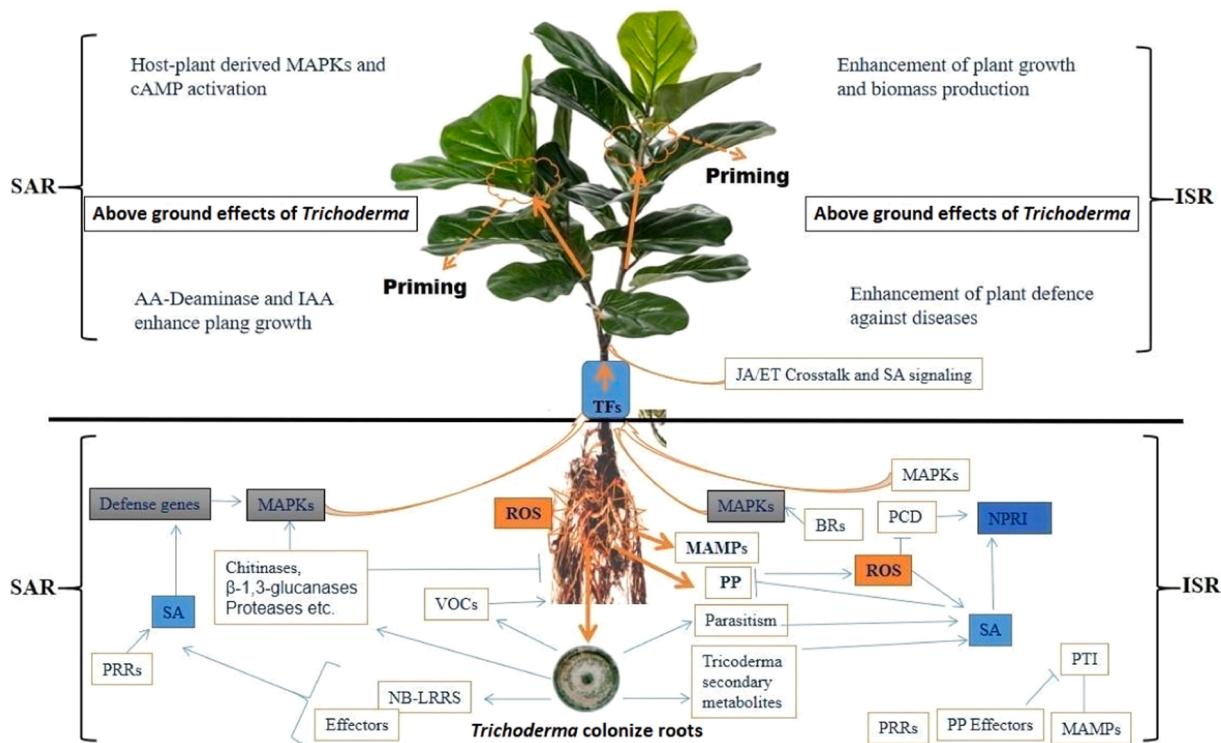

Fig. 2. Mechanisms of *Trichoderma* induced resistance and signaling pathways in plants against plant diseases. The Plant pathogens (PP) like bacteria, viruses or fungi can secrete various enzymes to degrade the plant's cell wall, and insight infection or develop feeding sites for their growth and multiplication. Some PP can also produce some effector proteins to suppress the plant triggered immunity (PTI). *Trichoderma* can inhibit PP by producing different kinds of toxic metabolites or directly parasitize on tissue, egg, hyphae, or cell of PP, they can as well produce some elicitor proteins or chemical signals like the salicylic acid (SA) or jasmonic acid (JA) to either enhance the plant's defense mechanism against the PP a process called The induce systemic resistance (ISR). Some PP-like nematodes can produce a high level of reactive oxygen species (ROS) to avoid cell death inside living cells or tissue, *Trichoderma* can help plants by triggering cell death around parts already colonized by the PP. In addition, another biocontrol mechanism of *Trichoderma* on PP is by induction of systemic acquired resistance (SAR) in plants. This they do by their interference with or triggering in plants, the production of the microbial-associated molecular pattern (MAMP), and volatile organic compounds (VOCs) which can also induce indole acetic acid (IAA) and 1-aminoacylpropane-1-carboxylate-deaminase (ACC-deaminase) secretion by plants. Others include the cell wall degrading enzymes (CWDEs) such as Chitinases, β -1,3 glucanases, and proteases, and induce mitogen-activated protein kinases (MAPKs). The cross-talk among the elements of SAR triggered pathogens and ISR signaling by *Trichoderma* can activate the plant defense response pathways of cyclo adenosine monophosphate (cAMP) and MAPKs from uninjected plant's part to the infected parts.

Induced systemic acquired resistance			

reported from the cacao tree, *Theobroma cacao* (Evans et al., 2003; Samuels et al., 2000; Gazis et al., 2010), and *Hevea brasiliensis*, rubber (Chaverri et al., 2011; Vaz et al., 2018) while many reports have presented novel species of *Trichoderma* from native Amazonian habitats, these species are capable of producing varieties of metabolites ranging from plant defense elicitors, mycotoxins to antibiotics (Chaverri et al., 2011; Schuster et al., 2010).

Mycoparasitic attributes of many *Trichoderma* strains have been established and have been well explored for the biological control of

various plant pathogens (Howell et al., 2003). Many of such strains are now packaged under different trade names for the usage of farmers. *T. stromaticum* is a notable example patented as 'Tricovab' for the control of fungus *Moniliophthora perniciosa* causing the witches' broom disease of cacao which is the major problem of cacao in Neotropics (Souza et al., 2006; Samuels et al., 2012). This product has been well distributed to farmers in southern Bahia in Brazil for many years (Bettoli et al., 2012; Samuels and Hebbar, 2015) and has now been employed as part of the integrated pest management strategy for controlling cacao pests (Medeiros et al., 2010). Another prominent example is *T. harzianum* which can colonize and degrade sclerotia of many fungal pathogens (Elad et al., 1984; Druzhinina et al., 2011), this fungus has been widely distributed as bio-fungicide (Samuels and Hebbar, 2015; Whipps and Lumsden, 2001).

4. Trichoderma advocacy, commercialization, and regulations

Biocontrol activity involves a variety of biological control agents such as bacteria and fungi, among which the fungal genus, *Trichoderma*, is significant in the management of plant diseases. This fungus produces a variety of enzymes that aid in the biocontrol activities such as biotic and abiotic stress tolerance, cell wall disintegration, hyphal development, and antagonistic action against plant diseases. *Trichoderma* species are pervasive and frequently dominating components of the mycoflora in natural and agricultural soils across all temperate zones. They are resident in both the terrestrial and marine environment and have adapted to almost every ecology, and contribute significantly to the health status of the ecosystem. Species of *Trichoderma* colonize the plant endosphere and rhizosphere and have also been recovered from soil organic matter, plant litter, and human tissues (Mukherjee et al., 2013).

The capacity of *Trichoderma* fungi to function as biocontrol agents against plant diseases has been recognized as early as the 1920 s (Harman, 2006). The ability to detect, invade, and destroy other fungi are the reason for its economic success and commercial application, as *Trichoderma*-based biopesticides constitute over 60% of all registered biopesticides (Mukherjee et al., 2013). Apart from providing resistance against plant diseases, these fungi also increase plant growth and vigor, solubilize plant nutrients, enhance nutrient absorption in plants, and bioremediate heavy metals and environmental contaminants while producing clinically important secondary metabolites and enzymes to both human and plant safety (Singh et al., 2018; Sood et al., 2020). *Trichoderma* species are often employed as biological control agents against phytopathogenic microbes, including those which cause the tomato root rotting disease that is of interest in this study. They act through mechanisms such as antibiosis, mycoparasitism, and competition for space and resources, while their impacts on plants such as induced systemic or localized resistance are also of importance in the biological management processes (Howell, 2003). *Trichoderma* spp. are not only successful plant symbiotic organisms, but they also act as a low-cost, effective, and environmentally benign biocontrol agent. They may establish themselves in a variety of pathosystems, have a low influence on soil balance, and do not harm beneficial species that aid in pathogen management (Sood et al., 2020).

Trichoderma products are promoted as biofungicides, biopesticides, bioprotectants, bio-stimulants, bio-inoculants, bio-fertilizers, bio-decomposers, plant growth promoters, and so on (Woo et al., 2014). Some *Trichoderma* isolates such as *T. polysporum*, *T. harzianum*, *T. asperellum*, *T. atroviride*, *T. viride* *T. polysporum* are particularly known for their broad-spectrum biofungal potentials against a range of foliar, vascular, and soilborne diseases caused by *Rhizoctonia solani*, *Botrytis cinerea*, *Sclerotium* spp., *Sclerotinia sclerotiorum*, *Pythium ultimum*, *Armillaria* spp., *Phytophthora* spp., *Verticillium* spp., *Fusarium oxysporum* and *Gauemannomyces graminis* (Ghazanfar et al., 2018; Woo et al., 2014). These properties broaden the range of potential applications for *Trichoderma*-based products in the agricultural market, not only as a phytopathogen biofungicide, but also as a general bio-inoculant that

boosts plant resistance to biotic and abiotic stresses, improves plant growth and yield, and enhances the agro-ecosystem (Hill et al., 2010).

Despite its efficacy, *Trichoderma* as a biocontrol agent has its limitations. Although *Trichoderma* successfully colonizes the spermosphere, it does not thrive in the rhizosphere (Harman, 2000). Also, *Trichoderma* spp. are active only in certain types of soil and seasons, therefore achieving only transitory localized dominance of the rhizosphere. Moreover, the inactive and dormant nature of *Trichoderma* spores in soil suggests that *Trichoderma* cannot be supplied as spores (Aamir et al., 2020). In addition, various mechanisms have been uncovered in vitro, but the validity of such has not been successfully validated in the field of biocontrol systems (Woo et al., 2014). More so, biological control agents are fragile and could be denatured in hostile environmental conditions. Some of the measures to curtail these limitations are through adequate formulation. Hence the development of cost-effective, stable, and easy to apply biological control formulations is essential for the enhanced efficiency of the deployed biocontrol formulations (Lewis and Papavizas, 1987). The *Trichoderma*-based formulation in pelletized form is viable for over three months (Cuevas et al., 2001). It has been shown as effective against seedling diseases of vegetables caused by *S. rolfsii* when applied in pelletized form (Ram et al., 2020). In addition, *Trichoderma* formulations had also been commercialized as a wettable powder (WP), granular, powder preparation, liquid, and solids products. In contrast, others are emulsions, dry flowable, concentrated liquid suspensions, and talc, among others (Table 2) (Woo et al., 2014).

In general, the European Commission and other agencies around the world have indicated that about 38 *Trichoderma* commercial products (single species and combination mixtures) are registered or in the process of being registered in various countries, while four products have received special registration or temporary approval only for use in field experiments (Topolovec-Pintaric, 2019). Furthermore, the species of *Trichoderma* mostly present on the label of the commercial products are *T. atroviride*, *T. asperellum*, *T. hamatum*, *T. gamsii*, *T. koningii*, *T. harzianum*, *T. lignorum*, *T. polysporum*, *T. parceanammosum*, *T. viride*, *T. virens*, and *Trichoderma* spp. However, following the trend in the usage of several *Trichoderma* spp., nearly half of these new products contain *T. harzianum* (Bal and Altintas, 2006).

More than 250 *Trichoderma*-based products have recently been registered and identified on the international market (Ram et al., 2020). Yet, there occurs a huge disparity in the actual number of biological control agents in use compared to those registered. However, out of the *Trichoderma*-based registered products, Asia made the most significant contributions of 39%, and Africa, with nine registered products, had the least contributions of 3.5% among the regions of the world (Fig. 3). On the other hand, South Africa, Kenya, Zambia, Morocco, and Tunisia had registered and produced at least a *Trichoderma*-based product among the African nations (Table 2). While *Trichoderma* poses enormous promise in Africa, as evidenced in many scientific investigations into the genus conducted in the region, most African scientists and entrepreneurs seem not to be aware of the full potential of this product, especially in solving the peculiar cropping problem in Africa, as in the case of tomato farming. Hence, the smallholder farmers that constitute the bulk of agricultural productions in most African countries are stocked with chemical fertilizer in the face of non-viable and available organic alternatives.

Governing authorities across the globe, notably in Europe, are currently enacting legislation to reduce agriculture's reliance on pesticides to improve consumer and environmental safety. Directives will promote low pesticide input by implementing integrated pest management (IPM) and will provide the means to establish the necessary conditions and measures to employ these practices, as well as to ensure the security of commercial products, to reduce the risks associated with pesticide applications and reduce dependency on their use. As an alternative to synthetic agrochemicals, one strategy is to employ biological control agents and their products (Masip et al., 2013). Hence, *Trichoderma* species are qualified candidates, having been extensively

researched and one of the most widely employed microbial biological control agents (MCBAs) in Agriculture, and is presently marketed as biofertilizers, growth promoters, biopesticides, and natural resistance stimulants.

5. Gene pool to resistant varieties versus biological control agents: the constraints of African populace

5.1. Gene pool to resistant tomato varieties

The economic importance of tomatoes motivates genetically varied parents to achieve desired plant attributes such as increased yield, drought, disease resistance, and coping with other stressful situations such as harsh temperatures. The wild crop relatives have been domesticated over thousands of years. Some of the resulting cultivars have continued to hybridize naturally with their wild cousins to maintain stable agricultural production. This type of spontaneous gene flow aids in crop vigor and can lead to the genesis of new crops. Analysis of the genetic diversity of wild relatives and cultivated crops provides insight

into domestication's geographic and temporal details.

In contrast, its estimation may provide the basis for developing suitable strategies for crop conservation, improvement, and sustainable use (Tamburino et al., 2020), towards tomato cultivation less prone to disease in Africa. Plant breeders use genetically varied parents to achieve these qualities, as genetic variety is vital in tomato breeding (Plucknett and Smith, 2014). Meanwhile, the availability of enhanced cultivars that can tolerate biotic and abiotic pressures caused by the environment is critical for successful tomato (*Solanum lycopersicum*) production (Dube et al., 2020).

As in line with the standard practice in Africa, crop domestication either by natural or artificial selection reduces genetic diversity and eliminates many adaptive features present in wild counterparts (Meyer et al., 2012). While the selection of genotypes with desired character combinations that may exist in nature or through hybridization increases the productivity and quality of farmed tomatoes, the genetic diversity present in a crop collection needs to be estimated to improve the crop's genetics. The genetic examination of germplasm aids in interpreting a crop's genetic basis since there are interrelationships between characteristics that aids in the selection of essential yield contributing qualities. The breeder that is interested in specific features for the tomato improvement program such as the tomato resistance to root rotting disease in Africa will employ a gene pool that is considerably less varied than the overall available, with local germplasm known to contribute significantly to genetic variation (Kouam et al., 2018). Molecular approaches for assessing genetic variations have been employed for decades. High throughput DNA sequencing technology has lately given a tremendous boost to assessing genetic and adaptive variation in crops and model organisms (Meyer et al., 2012). Since the genome has already been linked to morphological and metabolic variation, the availability of tomato genomes, together with its phenotypic and molecular characterization, permits genome-wide association analyses to be developed (GWAS). The genome has already been linked to morphological and metabolic variation, according to GWAS studies (Mata-Nicolás et al., 2020) (Table 3).

Genes code for proteins and execute specific roles in all living creatures. Biocontrol genes regulate certain signals and cause the production of enzymes or proteins that aid in pathogen degradation. *Trichoderma* species have genes that can be exploited to offer resistance to biotic and abiotic stressors, including salt, heat, and drought, which are the most prominent problem of tomato in Africa. Some of the major types of

Adapted from: Woo et al. (2014).

biocontrol genes that can be easily isolated, cloned and characterized includes chitinase, protease, tubulins, glucanase, proteinase, monooxygenase, galacturonase, xylanase, cell adhesion proteins, and stress-tolerant genes, they play specific functions in the biocontrol mechanism such as hyphal growth, cell wall degradation, parasitic activity and cell wall degradation (Sharma et al., 2011). The biocontrol genes can be cloned and manufactured in huge quantities for commercial use (Sharma, Kumar et al., 2011; Srivastava et al., 2014).

Pozo et al. (2004) cloned *tvsp1*, a gene from *T. virens* encoding serine protease into *E. coli* using a pET-30 vector, this strain was used to induce resistance of tomato plant against *Rhizoctonia solani* (tomato blight pathogen), the gene according to them also enhance degradation of the pathogen cell wall. In another study, *tri5*, a tricodiene synthase gene was isolated from *T. harzianum* and cloned into a pGEMT vector for controlling the *Fusarium* pathogen of tomatoes (Gallo et al., 2004). Likewise, the expression of *tag83* gene encoding cell wall degrading enzyme exo- β -1,3-glucanase and from *T. asperellum* (Marcello et al., 2010).

Genetic engineering has also been used to enhance the biocontrol abilities of *Trichoderma* fungi. In a study, *T. virens* strains that were transformed with *TvBgn2* and *TvBgn3*, which are genes that encode β -1,3 and β -1,6 glucanase, efficiently inhibited the growth of *R. solani*, *Rhizopus oryzae*, and *Pythium ultimum*, according to Djonovic et al. (2007a), (2007b). Likewise, Donzelli et al. (2001) using pGEM-T vector, successfully cloned an antifungal glucan1,3- β -glucosidase gene called *gluc78* into *T. atroviridae* cells for effective biocontrol of several plant pathogens. This gene was in another study carried out by Saadia et al. (2008) was also cloned a glucose repressor gene from *T. harzianum* and cloned it into *E. coli* for expression of cellulase and xylanase from pathogens using pTZ57R/T plasmid vector. Several other works that have reported various genes in *Trichoderma* for the control of plant pathogens are presented in Table 4.

However, there is a need for adequate knowledge of the biocontrol mechanism of a specific species before its employment as a commercial product (Zaidi et al., 2014). Although, reports from some earlier studies had recognized *Trichoderma harzianum* as the most effective biocontrol agent among the *Trichoderma* species (Sharma, Kumar et al., 2011).

6. Future perspectives

New contributions of new valuable *Trichoderma* species are being

made yearly thanks to molecular or genome analysis. Valuable genes, related to biological control potentials, their defense induction in plants, or stress tolerance, have been identified using these methods. These genes can hence be enhanced using the advancing biotechnological/genetic tools. Their example of the gene that controls complex mechanisms used by *Trichoderma* against pathogens, for example, *T. atroviride* (Fanelli et al., 2018). In other studies, it was revealed that the bioactivity of secondary metabolites produced by some *Trichoderma* strains helps attack plant pathogens, and the genes that control the secretion of these metabolites were cloned in bacterial cells. Likewise, the metabolites of *T. viridae* and *T. pseudoharzianum* (T113) were toxic against the eggs of *M. incognita* (Khan et al., 2020). More than twenty species of *Trichoderma* were reported to be able to secrete about 390 important non-volatile nematicidal metabolites (Li et al., 2019). In tomato plants, *T. harzianum* T22 and *T. asperellum* T-34 strains were employed for systemic resistance induction against *M. incognita*. This was reflected in the over-expression of *Mi-1.2* gene in the inoculated tomato plants (Pocurull et al., 2020).

Trichoderma genus is already a well-known group of fungi with known importance and applications for sustainable agriculture. It is one of the most studied groups of fungi for use as plant disease control. They can evolve quickly with diversified metabolic pathways leading to the production of several bioactive compounds, enzymes, and secondary metabolites that can, in addition, be explored for human benefits. They have vast importance with potential value commercially and industrially apart from their importance in agriculture. Their ability to produce commercially important enzymes like amylases, cellulases, glucanases, and chitinases are reported every year with interesting results (Harman et al., 2004). Recently, they have been associated with the production of siderophores and silver nanoparticles (Maliszewska et al., 2009; Vahabi et al., 2011). More than 200 species have been reported as biopesticides (Bissett et al., 2015), while many have been well packaged commercially for use as biofungicides (Samuels and Hebbar, 2015).

The mass production of *Trichoderma* is of interest due to its valuable application in the biological control of plant disease pathogens. Commercial production of these bioagents has now come into reality, and several formulations have been reported (Table 1). The potential of *Trichoderma* as a tool for managing the plant's pest is now widely recognized globally. However, this approach has virtually not been well implemented in the management of many tropical crops, especially in

Table 4

Biocontrol genes that have been isolated or expressed in Trichoderma strains and their functions.

S/N	Biocontrol gene	Trichoderma strain	Function	Reference
1	<i>tga1</i> gene	<i>T. atroviride</i> strain P1ATCC 74058	Chitinase formation and production of antifungal metabolites	Reithner et al. (2005)

9	Endopolygalacturonase ThPG1 gene	<i>T. harzianum</i> T34 CECT 2413	Secretion of plant cell wall degrading enzymes against <i>R. solani</i> and <i>P. ultimum</i>	Moran Diez et al. (2009)
10	Endo-β-1-6-galactanase gene	<i>T. viride</i> IFO31137	A type of arabinogalactan proteins that involves in cell-cell adhesion, expansion and cell death.	Kotake et al. (2004)
11	Enzymology Group collection, UFG-ICB, tag 3 gene	<i>T. asperellum</i>	Production of cell wall degrading enzyme glucanase	Marcello et al. (2010)
12	<i>erg1</i> gene	<i>T. harzianum</i> CECT 2413	Silencing of the <i>erg1</i> gene enhances resistance to terbinafine that shows antifungal activity	Cardoza et al. (2006)
13	Genes encoding for NAGases (exc1 and exc2), chitinases (chit42 and chit33), proteases (prb1) and b-glucanases (bgn13.1)	<i>T. harzianum</i> CECT 2413	Mycoparasitic activity against <i>F. oxysporum</i>	Modezar et al. 2011
14	Mitogen Activated Protein kinase gene, <i>TmkA</i>	<i>T. virens</i> strain IMI 304061	Biocontrol activity against pathogens like <i>S. rolfsii</i> and <i>R. solani</i>	Mukherjee et al. (2003)
15	monooxygenase gene	<i>T. hamatum</i> LU593	Antagonist activity against <i>S. sclerotiorum</i> , <i>S. minor</i> and <i>S. cepivorum</i>	Carpenter et al. (2008)
16	proteinase gene <i>prb1</i> and endochitinase gene <i>ech42</i>	<i>T. harzianum</i> strain IMI206040	Regulation of hydrolytic enzymes to enhance parasitism of Trichoderma against Sclerotium rolfsii and Rhizoctonia solani	Cortes et al. (1998)
17	<i>qid74</i> gene	<i>T. harzianum</i> Rifai CECT 2413	Involved in cell protection and adherence to hydrophobic surfaces that helps in antagonism against <i>R. solani</i>	Rosado et al. (2007)
18	serine protease gene SL41	<i>T. harzianum</i>	Biocontrol activity against pathogens	Liu et al. (2009)
19	Sm1 gene, cysteine-rich protein	<i>T. virens</i> strain TvSMOE38	A small cysteine-rich protein that induces defense responses in dicot and monocot plants and in protecting crop diseases	Buensantei et al. (2010)
20	T34 hsp70 gene	<i>T. harzianum</i> CECT 2413	Increases fungal resistance to heat and abiotic stresses	Hermosa et al. (2011)
21	TaabC2 gene	<i>T. atroviride</i> P1 (ATCC 74058)	Plays key role in antagonism against <i>R. solani</i> , <i>P. ultimum</i> , and <i>B. cinerea</i>	Ruocco et al. (2009)
22	<i>tac1</i> , adenylate cyclase gene	<i>T. virens</i> IMI 304061	Mycoparasitism against <i>R. solani</i> , <i>S. rolfsii</i> , Pythium spp. and production of secondary metabolism	Mukherjee et al. (2007)
23	TgaA, TgaB genes	<i>T. virens</i> strain IMI 304061	Antagonism against <i>S. rolfsii</i> and <i>R. solani</i>	Mukherjee et al. (2004)
24	Th-Chit gene	<i>T. harzianum</i>	Antifungal activity in transgenic tobacco	Saiprasad et al. (2009)
25	Thctf1 transcription factor gene	<i>T. harzianum</i> CECT 2413	Antifungal activity against <i>R. solani</i> , <i>Fusarium oxysporum</i> and <i>B. cinerea</i> and production of 6-pentyl-2 H-pyran-2	Rubio et al. (2009)
26	Thke11 gene	<i>T. harzianum</i> CECT 2413	Expression of this gene in <i>A. thaliana</i> modulates glucosidase activity, and enhances tolerance to salt and osmotic stresses	Hermosa et al. (2011)
27	<i>tmkA</i> gene	<i>T. virens</i> IMI 304061	Induction of plant systemic resistance and biocontrol activity against <i>R. solani</i> . (Tested in green house condition)	Viterbo et al. (2004)
28	TrCCD1 gene	<i>T. reesei</i> QM9414 (ATCC 26921)	Helps in hyphal growth, conidiospore development and carotenoid pigment production.	HuaZhong et al. 2009
29	<i>tri5</i> gene	<i>T. brevicompactum</i> IBT40841	Production of trichodermin and antifungal activity against <i>C. albicans</i> , <i>C. glabrata</i> and <i>A. fumigatus</i>	Tijerino et al. (2011)
30	Trichodiene synthase gene, <i>tri5</i>	<i>T. harzianum</i> strain ATCC 90237	Production of toxin for inhibiting DNA or protein synthesis, and enhances virulence against <i>Fusarium</i> spp.	Gallo et al. (2004)
31	TvBgn2 and TvBgn3 genes	<i>T. virens</i> Gv29-8	These genes help in encoding cell wall degrading enzymes	Djonovic et al. (2007a), (2007b)
32	TvGST glutathione transferase gene	<i>T. virens</i> (strain IMI 304061)	Enhances cadmium tolerance in plants	Dixit et al. (2011)
33	Xylanase gene, <i>Xyl</i>	Trichoderma strain SY	Helps in breakdown of hemicellulose	Min et al. (2002)
34	β-1,4-endoglucanase gene, <i>egl1</i>	<i>T. longibrachiatum</i> strain CECT2606	Cell wall degrading enzyme for inhibition against <i>Pythium ultimum</i> on cucumber.	Migheli et al. (1998)

Africa. Most of the studies that investigated and reported the diversity of endophytic *Trichoderma* strains on different plant hosts were based on surveys restricted to the United States, Hawaii, and other countries other than the Africas. However, Africa is rich in biodiversity of different plants, which could also be rich in novel species of *Trichoderma*. For example, del Carmen et al. (2021) and Schulz and Boyle (2005) investigated the endophytic fungi associated with coffee plants observing that the fungi from America and Hawaii were dominated by *Colletotrichum*, *Fusarium*, *Penicillium*, *Pestalotia*, and *Xylaria* species which are in most cases existing as opportunistic endophytes of their host plants. The study from Africa in contrast, yielded more of *Trichoderma* as endophytic fungi; in detail, they reported endophytic *Trichoderma* from the aerial tissues of coffee plants, including four new species (Leylaie and Safari, 2018). The new taxa described by these authors may be geographically restricted to Africa or even to coffee plants.

The Africans are rich in diversity of *Trichoderma*, especially in the Neotropics. Some studies have reported a close association between *Trichoderma* species and *C. arabica* from Ethiopia (Mulaw et al., 2010, 2013). These studies focused majorly on the rhizosphere and root tissue species. They reported several species of *Trichoderma* such as *T. asperelloides*, *T. atroviride*, *T. gamsii*, *T. hamatum*, *T. koningiopsis*, *T. longibrachiatum*, *T. spirale*, and *T. sensulato*. *T. hamatum*, *T. spirale*, and *T. koningiopsis* are cosmopolitan species commonly associated with stems, leaves, berries from tropical habitats and the soil (Kubicek et al., 2003; Hoyos-Carvaljal et al., 2009; Samuels et al., 2006; Druzhinina et al., 2005). Some species, such as *T. koningiopsis* and *T. spirale* have been isolated from more than one plant tissue from the leaf and stem of *C. canephora*, *C. arabica*, and tomatoes. Other reports have also identified *T. koningiopsis*, *T. hamatum*, and *T. spirale* as endophytes of tropical woody plants, notably cacao and rubber (Samuels and Hebbar, 2015). *T. atroviride*, *T. guizhouense*, *T. breve*, and *T. theobromicola* are very common in the tropical soils, mushroom compost, in leaf-cutting ant colonies decaying wood and bark, they have also been reported as endophytes of *Theobroma* sp. (Malvaceae) (Samuels and Hebbar, 2015; Chaverri et al., 2015; Montoya et al., 2016).

T. theobromicola is an endophyte of cacao sapwood native to South America (2006; Almeida et al., 2018), while *T. breve*, native to China was recently isolated from soil (Chen and Zhuang, 2017). They both have been reported as new geographical pantropical endophytes from Africa (del Carmen et al., 2021). Many *Trichoderma* such as *T. atroviride*, *T. hamatum*, *T. longibrachiatum*, *T. reesei*, and *T. virens* have been characterized as mycoparasitic fungi (Mukherjee et al., 2013; Kubicek et al., 2019). They have a wide host range against several plant pathogenic fungi like *Alternaria alternata*, *Botrytis cinerea*, *Fusarium* sp., *Rhizoctonia solani*, as well as the Oomycetes like *Pythium ultimum* (Karlsson et al., 2017). Those from Africa as revealed by del Carmen et al. (2021) included *T. aggressivum*, *T. andinense*, *T. parareesei*, *T. petersenii*, and *T. pseudopyramidal* are mycoparasites of *H. vastatrix* and can also attack *Hemileia* rusts of coffee plants. Other mycoparasitic *Trichoderma* species isolated by these authors from Africa were *T. atroviride*, *T. hamatum*, and *T. virens*. *Trichoderma pseudopyramdale*. Authors advocated that these fungi from Africa deserved attention with vast potential for use in the biological control of plant diseases.

While many reports are identifying native *Trichoderma* strains from Africa, there is limited information on their new capabilities or details on their potential application or mechanism of action. Most studies from Africa are data monitoring experiments without an in-depth characterization of the fungi actions. Information on the ecology of *Trichoderma* species from Africa at large is relatively circumscribed del Carmen et al. (2021), in their work, observed that about 60% of their isolated plant endophytic fungi of wild coffee from both Cameroon and Ethiopia were *T. botrys* and *T. pseudopyramdale*. These strains were reported as good mycoparasites of *Hemileia* rusts and suggested for use as the biological control in Central America, where this disease is endemic on coffee plants (Avelino, 2015; Ward et al., 2017; Oxfam International, 2014). There are claims that native *Trichoderma* bioagents can be more

virulent on foreign plant pathogens or vice versa (Jackson et al., 2012). However, the diversity of *Trichoderma* in Africa is still not well studied, as compared to other parts of the world (Sadfi-Zouaoui et al., 2009). To date, only a few species are reported from Africa, while there are fewer in-depth works on a wide range of characterization of *Trichoderma* from natural habitats in Africa (Askew and Laing, 1994; Chaverri and Samuels, 2004; De Respins et al., 2010; Mutawila et al., 2011). Most of the few reports of native African *Trichoderma* species were not on its biodiversity on large geographical areas but majorly on either in-vitro biological control or application on a few study areas. Only a few studies in Africa isolated *Trichoderma* from natural habitats or outside soil environments.

The genetic pool of major bioagents in this group are those from the above-ground habitat (López-Quintero et al., 2013). There is limited information about the ecology of new strains. *Trichoderma* species from Africa in general coupled with their potential application. The shelf-life of these bioagents under different formulations is a significant factor affecting their commercial distribution. *T. harzianum* and *T. viride* are well-known bioagents in different formulations. They have been grown on solid substrates like wheat straw, wheat bran, coffee husk, sorghum grains, and much other biomass to enhance their life span. Fermented molasses and brewer's yeast were suggested to prepare *Trichoderma* formulations (Agosin et al., 1997; Carmen et al., 2021) while some organic matter farmyard manure, as well as seasoned press, have also been suggested.

Most African nations had instituted integrative programmes tailored towards enhancing agricultural practices but most of the programmes failed. It should be noted that the result of an unending cycle of restructuring and recapitalization in agricultural production inputs as commonly practice, would be short lived when dynamic approach in disease management practices are not embraced. Hence, Africa's agricultural prosperity is hinged on her embracing indigenous bioresources in pest and disease management such as *Trichoderma*-based formulations investigated against tomato root rot in this review. More so, it is essential to reinforce the existing interlinked network system among the researchers, extension workers and farmers, to aid the timely acceptance and utilization of indigenously developed biological control agents to attain optimum production.

7. Conclusion

Africa contributes immensely to the global supply of tomatoes, yet many of its productions are inhibited either by abiotic or biotic stressors. While the adoption of bioagents as eco-friendly management of crop diseases is gaining global acceptance, most African countries still rely on chemical-based treatments. Whereas, *Trichoderma* has been recognized for its effectiveness in plant disease management, instilling of disease resistance, and enhancement of plant growths, among other researched qualities. To date, Africa has the least number of registered and commercialized *Trichoderma*-based formulations that have been engineered as broad-spectrum or specific targets such as the root rot of tomato. The peculiar constraints limiting agricultural productions in the African nations need to be addressed. More so, there calls for urgent collaborative efforts among the African governments, researchers, and the stakeholders in agriculture, to research into indigenous *Trichoderma*-based formulations, register and commercialize it while ensuring an enabling environment for its use and the smooth sailing of agricultural activities for both small- and large-scale farmers.

Author Contributions

All authors listed have made a substantial, direct, and intellectual contribution to the work and approved it for publication.

Funding

OOB recognizes National Research Fund (NRF South Africa) for grants (UID123634 and UID132595) that support work in her research group.

Declaration of Competing Interest

The authors declare that the research was conducted without any commercial or financial relationships that could be construed as a potential conflict of interest.

Acknowledgment

OMO appreciates the Centro Internazionale Cooperazione per lo Sviluppo (CICOPS) of the University of Pavia for financing her research in the Department of Earth and Environmental Sciences, University of Pavia, Italy. She also thanks Prof Solveig Tosi of Mycology Laboratory, Department of Earth & Environmental Sciences, University of Pavia, Italy, for her supervisory role in the research and manuscript writing.
